Landslide susceptibility in fine-grained sediments

- Slope less than 5 percent.
- Slope equal to or greater than 5 percent.

Landslide susceptibility in other sediments

- Slope less than 5 percent.
- Slope equal to or greater than 5 percent.

Slope
- Slope is the primary driving force for landslides and earth movements. Slope is defined as the inclined surface of the land. The steeper the slope, the larger the shear stress produced by the weight of the materials and the more susceptible the slope is to failure. For this map, a slope of 5% or greater is considered a risk factor.

Slope aspect
- Slope aspect is the direction toward which the surface of the soil faces. South-facing slopes undergo more extensive freeze/thaw cycles in winter months than slopes with other aspects. Repeated freeze-thaw cycles preferentially reduce the shear strength of the shallow soil material and increase the likelihood of shallow soil slumps. Ultimately, small movements may steepen the slope and lead to larger slope failures. For this map, a slope aspect between South 45° East and South 45° West is considered an additional risk factor.

Curvature (concave shape)
- Hill shape influences landslides by its effects on soil and water distribution. Concave surface topography will tend to concentrate the flow of surface water and ground water, raising ground-water pore pressures and reducing the shear strength of the soil. As a result, concave slopes are more susceptible to failure than straight slopes or convex slopes. For this map, a concave shape is considered an additional risk factor.

Local relief (slope height)
- As the thickness of the potential landslide block increases, the steeper the slope on the lower section of the block increases and the block (or slope) is more susceptible to failure. As a consequence, thicker sections of superficial sediments will be more susceptible to failure and possibly deeper and larger failures. For this map, local relief greater than 6 meters (approximately 20 feet) is considered an additional risk factor.

Sites of past landslides

The purple area delineates the extent of the landslide and the letter indicates the type of landslide, defined in the diagram entitled Common Types of Landslides in Maine. Two or more letters indicate multiple processes were involved at the site or contributed to landslide morphology. Past landslides were mapped from aerial photo interpretation and field investigations in 2008.

Mapped landslides in the town of Eliot

This map can be used to identify areas with historical landslide activity and to identify areas that are susceptible to future landslide activity where additional studies should be undertaken before construction or other development is started that could be at risk due to a future landslide. Nearly 50 percent of mapped landslide sites in the town of Eliot (19 of 20 features) are located in areas shown as having a slope of 5 percent or more, and 88 percent of the mapped landslide sites are located in areas containing at least one additional geomorphic risk factor.

From this, we conclude that there is a significantly greater risk of a landslide occurring in areas containing one or more of the geomorphic risk factors than in areas that do not contain any of these risk factors.

Sources of information used to make this map

Terrain-related risk factors were calculated from the National Elevation Dataset 1/3 Arc Second product developed and published by the U.S. Geological Survey. The horizontal resolution of the 1/3 Arc Second dataset is approximately 10 meters. This digital elevation data is accurate to within 7.5 meters or ±7 meters (approximately 20 feet) is considered an additional risk factor.

Common Types of Landslides in Maine

- Rotational landslide
- Translational landslide
- Rockfall
- Debris flow
- Creep (Flow)

Funding for the preparation of this map was provided by the Maine Emergency Management Agency.

Limitations of the data

This map may be used to identify areas that are susceptible to landslide activity. Based on the risk factor analysis, if a landslide or earth movement does occur, it is very likely to be in the areas containing one or more of the geomorphic risk factors shown on this map, but it is not possible at this time to predict whether a landslide or earth movement will occur.

The landslide site mapping and risk factor analysis were done in 2008. Some mapped landslides may have occurred since the photography and digital elevation model were mapped or generated.
