Pruning White Pine
A Reference Guide for Foresters

Maine Forest Service, DEPARTMENT OF AGRICULTURE, CONSERVATION & FORESTRY,
22 State House Station, Augusta, ME 04333

Pruning is removing branches of a standing tree flush with the outside of the branch collar. When pruning is done to increase income, trees that will grow to sawtimber size and quality are pruned.

Why prune?
White pine can be pruned to improve the health and appearance of a tree, or to increase its commercial value. Pruning of trees destined for a lumber or veneer mill can be very profitable. It improves value by:

♦ Increasing production of high grade clear wood.
♦ Reducing stem taper.
♦ Reducing damage potential from disease agents such as white pine blister rust.

When to Prune.
It is best to begin pruning white pine when the tree is young and the branches are small. This allows the most clear lumber to grow on the bole, since knots form as each year's new growth surrounds a living or dead branch. Also, it is easier, more efficient and healthier for the tree to prune small branches regularly than to prune large limbs. Usually the tree should be pruned after it is at least 4 inches at DBH. Pruning operations may be repeated regularly until the lower 17’ to 25’ of the bole (higher on very productive trees) has been pruned. Never remove more than 1/3 of the live crown.

Economic Benefits of Pruning
The commercial value of crop trees can be greatly increased by pruning—studies have shown that stumpage values can be increased 20 to 25%. It is generally not profitable to prune trees that will be removed in intermediate thinnings. The following table shows the ratio of clear and knotty lumber per 1,000 board feet grown on trees pruned at different diameters.*

<table>
<thead>
<tr>
<th>Diameter of Knotty Core</th>
<th>Board Feet of Clear Lumber</th>
<th>Board Feet of Knotty Lumber</th>
</tr>
</thead>
<tbody>
<tr>
<td>3 inch</td>
<td>920</td>

<td>NONE</td>
<td>1000</td>
</tr>
</tbody>
</table>

* Measured on logs 12" in diameter at the small end and 14’ long. Harvard Forest Bulletin, "Pruning for Profit as Applied to Eastern White Pine." Other studies on small samples of white pine in Maine found, after adjusting for taxes and inflation, 13.5% and 13.65% increases in value of pruned as compared to unpruned trees.

How to Prune

Record Keeping

♦ Make sure you or your landowner keep good records of which trees are pruned and when they are pruned.

♦ Pruning records will alert the mill to your pruned logs’ value. Logs that look the same on the outside may have significantly different worth. Logs with more years of post-pruned growth have more clear lumber and higher value.

♦ Remind your landowner that notarized records can be entered into the local registry of deeds miscellaneous book. Records are less apt to get lost and they might be a valuable record for landowners or heirs.

♦ Not every mill will recognize the extra value of previously pruned pines. It is important for you and the landowner to search out those pine mills that do pay extra for these trees, and to check with these mills.

Practical advice for your land and trees from the Maine Forest Service
before the harvest to find out what they need for records. Sometimes mills will send out a representative before the harvest to check on the condition of these trees.

**Tree Selection**
- **Marking** trees to be pruned before pruning will save time and labor costs.
- **Prune only dominant trees with healthy crowns that receive direct sunlight on their tops and at least partial sunlight on their sides.**
- Trees to be pruned must be released from competition before, or at the time they are pruned. If this is not done, many pruned potential crop trees will end up as intermediate or suppressed trees that will be thinned out of the stand before they have a chance to grow enough clear wood to justify the work of pruning. **One of the criteria for choosing trees to be pruned should be picking only trees that are planned to remain growing in the stand for at least another 20 years.**
- Prone only trees with straight, upright trunks, and no splits, forks, other defects, or branches larger than 2 inches in diameter within the first 9 to 17 feet of trunk.
- Trees to prune should be at least 4 inches at DBH and no more than 12 inches at DBH, although exceptionally thrifty, dominant, small limbed pines up to 16 inches could be done.
- Plan on pruning at least 100 trees future crop trees per acre (approximately 20' x 20' spacing) where species and stem conditions permit. To maintain stocking, where possible prune an additional 50 trees well distributed over an acre, for a total of 150 trees per acre.

**Pruning Equipment**
- Never prune with an ax. Use a pruning saw. Small dead branches and branches within 6 feet of the ground are easily removed with a hand saw. A lightweight power saw in skilled hands is effective on lower branches, but care must be used to avoid damaging the tree. For safety, do not attempt to prune higher limbs with a power saw. Prune to the desired height with a pole pruning saw.
- Always use a hard hat and eye protection when pruning.

For good equipment from a forestry supplier, a hand pruning saw may cost from $20 - $60; a pole pruner from $35-$200.
