Covering the area from Sanford, Maine, to the south boundary of the quadrangle

February 1997

The surficial geology of the Sanford Quadrangle, Maine, was mapped during 1992 as part of an ongoing study of the surficial geology of the state of Maine. The map covers an area of approximately 25,000 acres, located in the townships of Sanford and Limington, Maine. The map shows the distribution of surficial materials, including glacial drift, till, boulder clay, outwash, and Colluvium. The map also shows the location of surficial geologic features, such as eskers, kames, and moraines. The map is useful for understanding the landscape development and the history of glacial activity in the area.
